**Supplementary Video S1**—Laryngeal endoscopy in a Beagle anesthetized with propofol and dexmedetomidine. A laryngeal mask airway was placed, and a flexible endoscope passed through the lumen and placed rostral to the larynx. The left recurrent laryngeal nerve was identified with ultrasonography and electrolocation; elicited responses to nerve stimulation can be observed on the left side superimposed over abduction during spontaneous breathing, confirming correct placement of the needle. Lidocaine was injected perineurally to induce reversible laryngeal hemiplegia.
