

Supplementary Figure S1—Project timeline. Those horses supplying the treatment ligaments (A & B) were euthanized at 120 days after being denervated. Five suspensory ligaments injected with collagenase 162 days earlier (and denervated 42 days later) were assigned to treatment group B. The 5 contralateral ligaments that had been only denervated were assigned to treatment group A. Ten control ligaments were harvested from 5 horses that had not undergone neurectomy of the DBLPN.
